

# Blog Project

## Project Brief

This project is a full stack Blogging app that will allow the user to create, view, update and delete blog posts.

## Your Project

The Blog App should include the following functionality:

1. A single page application.
2. Visitors arriving at the site are presented with a list of all blog articles.
3. There is the ability to log in.
4. The App will pass login credentials to the API which will check these against the db.
5. A logged in user in addition to the basic view will be able to:
  - a. Add a new blog post
  - b. Update an existing post with new information
  - c. Delete a post
6. Each event should include the following information:
  - a. Title
  - b. Date
  - c. Post text
  - d. Date of post
  - e. Tags to label the blog content.

## Deliverables

The GitHub Pages URL for the front end

The GitHub Repository URL for Front end, and the API

## Extension

The app could be extended by allowing the user to view posts by tag or date, or search for an individual blog post by title.

If you really want a challenge you could allow multiple users access but only the ability to update or delete their own posts. You could extend this further by adding the creation of new users to the frontend app.
